The Covid19Analytics project

Goals

- Develop a tool to aid the Covid-19 crisis management in Brazil and inform the public.
- Forecasts for confirmed cases and deaths.
 - ★ Country-level and state-level
 - ★ Forecasting for up to 14 days.
 - ★ Forecasts for groups of municipalities according to their development level.
- Reproduction number calculation.
 - ★ State-level and country-level.
 - ★ Groups of municipalities
 - ★ Health regions

The Covid19Analytics project

Goals

- Set of descriptive statistics and under-notification analysis .
- Covid-19 and economic indicators.
- Daily updates.
- Forthcoming: Nowcasting new deaths and cases.
 - ★ Based on “SRAG” data

Forecasting Model

Motivation

Why Short-Term Forecasts?

Being able to forecast accurately the number of Covid-19 cases and deaths in the very short-run is crucial to manage properly the health system.

- More informed decisions on how to allocate hospital beds and ventilators, on whether to set more field hospitals, on whether to train more health workers, etc.
- Simple statistical model for **short-term real-time forecasting** of the number of Covid-19 **cases and fatalities** in countries that are *latecomers*
 - ★ i.e., countries where cases of the disease started to appear some time after others

The Model

Pros and Cons

Pros

- “Structure-free”: avoid tuning of too many parameters
- Data speak for themselves.
- Focus on individuals pressing the health system.
- Simple and cheap to be implemented.

Cons

- Sensitive to structural breaks: the model will take a few days to adapt
- Sensitive to outliers.
- No information about lockdown timing or other policies (although this can be incorporated)

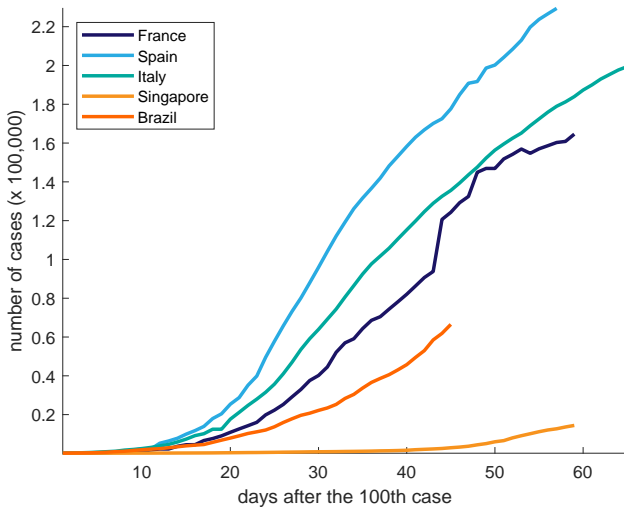

The Model

Data in Calendar Time

The Model

From Calendar Time to “Case Time” (# of days after the 100th case)

The Model

Other Countries are Ahead of Brazil

The Model

Forecasts (Partly) Based on Future Dynamics

The Model

How Many Countries Are in Fact Ahead?

- 31 countries ahead of Brazil

- ★ 17 countries 7 days ahead of Brazil:

- China, France, Germany, Iran, Italy, Japan, South Korea, Netherlands, Norway, Singapore, Spain, Sweden, Switzerland, USA, United Kingdom

- ★ 7 countries 14 days ahead of Brazil:

- China, France, Iran, Italy, Japan, Singapore, South Korea

- We have discarded China and France

- There are 152 countries behind Brazil. The methodology can be applied to these cases as well.

The Model – First Generation

Log-linear Error-Correction

$$\Delta y_{\tau} = \Delta \mathbf{x}'_{\tau} \boldsymbol{\pi} + \gamma (y_{\tau-1} - \mathbf{x}'_{\tau-1} \boldsymbol{\beta}) + u_{\tau}$$

- Daily growth rate (in “case time”) in the number of confirmed cases is a function of:
 - ★ daily growth rate (in “case time”) in the number of confirmed cases from a pool of peers (other countries);
 - ★ discrepancy between the target country and the peers in the previous day (**in logs**).
- Remember that the peers are ahead of time from the target in “case time”.

The Model – First Generation

Log-linear Error-Correction

$$\Delta y_{\tau} = \Delta \mathbf{x}'_{\tau} \boldsymbol{\pi} + \gamma (y_{\tau-1} - \mathbf{x}'_{\tau-1} \boldsymbol{\beta}) + u_{\tau}$$

- **Daily growth rate** (in “case time”) in the number of confirmed cases is a function of:
 - ★ daily growth rate (in “case time”) in the number of confirmed cases from a pool of peers (other countries);
 - ★ discrepancy between the target country and the peers in the previous day (**in logs**).
- Remember that the peers are ahead of time from the target in “case time”.

The Model – First Generation

Log-linear Error-Correction

$$\Delta y_{\tau} = \Delta \mathbf{x}'_{\tau} \boldsymbol{\pi} + \gamma (y_{\tau-1} - \mathbf{x}'_{\tau-1} \boldsymbol{\beta}) + u_{\tau}$$

- Daily growth rate (in “case time”) in the number of confirmed cases is a function of:
 - ★ daily growth rate (in “case time”) in the number of confirmed cases from a pool of peers (other countries);
 - ★ discrepancy between the target country and the peers in the previous day (in logs).
- Remember that the peers are ahead of time from the target in “case time”.

The Model – First Generation

Log-linear Error-Correction

$$\Delta y_{\tau} = \Delta \mathbf{x}'_{\tau} \boldsymbol{\pi} + \gamma (y_{\tau-1} - \mathbf{x}'_{\tau-1} \boldsymbol{\beta}) + u_{\tau}$$

- Daily growth rate (in “case time”) in the number of confirmed cases is a function of:
 - ★ daily growth rate (in “case time”) in the number of confirmed cases from a pool of peers (other countries);
 - ★ **discrepancy** between the target country and the peers in the previous day (**in logs**).
- Remember that the peers are ahead of time from the target in “case time”.

The Model – Second Generation

Log-linear Large Bayesian Vector Autoregression

- Framework: Bańbura et al. (2010).
- Set up a panel with all countries, states and provinces that do not have inconsistent data.
- Place the regions mentioned above in the epidemiological time with cases after 100 days.
- Filter only regions that are at least 14 days ahead of the most “backward” region in Brazil.
- Suppose that T_a is the last data in the epidemiological calendar of the most backward Brazilian state. The first model is estimated with data up to T_a , and forecasts are computed for T_{a+1} . However, in T_{a+1} , only the most delayed state is not observed yet. Therefore, the forecast is used only for this state.
- The next step is to re-estimate the VAR (rolling window) with data up to T_{a+1} and compute the predictions for T_{a+2} .

Where are we and to where are we going?

A second wave? Nowcasting the trend of new deaths

Nowcast de novos óbitos por data do evento

Where are we?

A second wave?

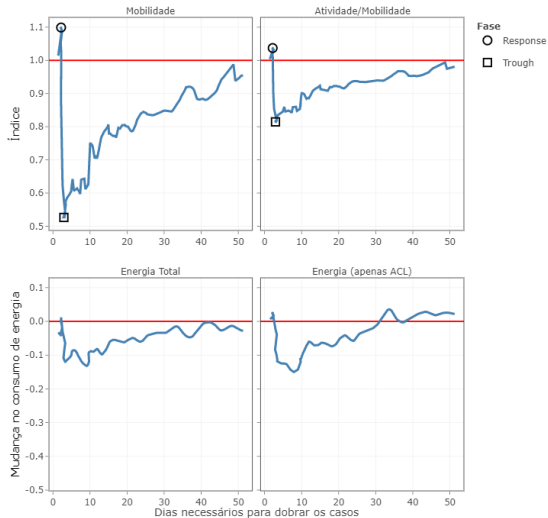

- There is no evidence of a **strong** second wave, but numbers are increasing.
- The increase in the number of cases and deaths seem to be more related to delays in the notifications.
- New hospitalizations were partly due to some changes in the rules, but now we can see a “real” increase in hospitalizations.
- Nowcasts show a small increase in the numbers.
